KAPLAN INTERNATIONAL COLLEGE LONDON – IYO COMPUTER SCIENCE PROGRAMME

Practical Assignment: Programming tasks

Module title: Computer Architecture
Module code: IY497
Assessment name: Practical Assignment: Programming tasks
Student name: Abdul Fatah Abdul Rauof Atar
Student ID: P456774

I confirm that this assignment is my own work.
Where I have referred to academic sources, I have provided in-text citations and included the sources in the final reference list.

Technical Overview

Task 1: Calculating A = π × R² × b ÷ 2

Q1

```
; This section define pi as a float, R value and b value
section .data
   pi dd 3.14
   R dd 5.0
   b dd 2.0
   half dd 2.0
   msg db "The result is: ", 0
   newline db 10
   buffer db 20

section .bss
   ; Reserve space to store the integer result
   int_result resd 1

section .text
   global _start

; This subroutine calculates A = (pi * R^2 * b) / 2 and saves it as an integer
calculate:
   fld dword [R]
   fmul st0, st0
   fld dword [pi]
   fmul st0, st1
   fld dword [b]
   fmul st0, st1
   fld dword [half]
   fdiv st1, st0
   fstp st1
   fistp dword [int_result]
   ret

_start:

   ; This block calls the subroutine to perform the calculation
   call calculate

   ; This block prints the message "The result is: "
   mov eax, 4
   mov ebx, 1
   mov ecx, msg
   mov edx, 15
   int 0x80

   ; This block changes the number to text so we can print it
   mov eax, [int_result]
```

```
    mov ecx, buffer
    add ecx, 19
    mov byte [ecx], 0

    ; This loop turns the number into text one digit at a time so we can print it
.convert_loop:
    xor edx, edx
    mov ebx, 10
    div ebx
    add dl, '0'
    dec ecx
    mov [ecx], dl
    test eax, eax
    jnz .convert_loop

    ; This block prints the actual number
    mov eax, 4
    mov ebx, 1
    mov edx, buffer + 20
    sub edx, ecx
    mov ecx, ecx
    int 0x80

    ; This the final part to exits the program
    mov eax, 1
    xor ebx, ebx
    int 0x80
```

```
; This section define pi as a float, R value and b value
section .data
    pi dd 3.14
    R dd 5.0
    b dd 2.0
    half dd 2.0
    msg db "The result is: ", 0
    newline db 10
    buffer db 20
```

This first block defines data for Q1 in the .data section. We see four floating-point values (pi, R, b, half) defined with dd directives. These are stored in memory as floats. We also define text strings, msg holds the prompt "The result is: ", newline is a line-feed character, and buffer reserves 20 bytes of space. Together, these will be used to print the result.

```
section .bss
    ; Reserve space to store the integer result
    int_result resd 1
```

This block is in the .bss section and reserves an uninitialized word for int_result. The resd 1 directive allocates one integer in memory. This space will hold the integer result after converting from floating-point. The comment clarifies its purpose. Since it’s in .bss, it is initially zeroed at program start, and does not consume file space.

```
section .text
    global _start

; This subroutine calculates A = (pi * R^2 * b) / 2 and saves it as an integer
calculate:
    fld dword [R]
    fmul st0, st0
    fld dword [pi]
    fmul st0, st1
    fld dword [b]
    fmul st0, st1
    fld dword [half]
    fdiv st1, st0
    fstp st1
    fistp dword [int_result]
    ret
```

This block defines the calculate subroutine for Q1. First, fld dword [R] loads the float R onto the top of the floating-point register stack. Then fmul st0, st0 squares it (R^2). Next, fld dword [pi] pushes π (3.14) onto the FPU stack and fmul st0, st1 multiplies it by the previous R^2 now st0 * st1 = π * R^2. Then fld dword [b] loads b, and fmul st0, st1 multiplies the result by b. After that, fld dword [half] loads the constant 2.0. The instruction fdiv st1, st0 divides the number in st1 by st0 (effectively (π*R^2*b)/2.0). Then fstp st1 pops the intermediate value so that only the result is left. Finally fistp dword [int_result] converts the top floating-point value to a integer and stores it at int_result. The ret returns control to the caller. In summary, this subroutine computes the formula A=(π·R^2 ·b)/2 and saves it as an integer.

```
_start:

    ; This block calls the subroutine to perform the calculation
    call calculate
```

This block is the entry point _start for Q1. It simply calls the calculate subroutine defined above. The call instruction pushes the return address on the stack and jumps to calculate.

```
    ; This block prints the message "The result is: "
    mov eax, 4
    mov ebx, 1
    mov ecx, msg
    mov edx, 15
    int 0x80
```

This block prints the static message "The result is: " for Q1. Linux syscalls are used: setting eax=4 selects the sys_write call, ebx=1 means file descriptor 1 standard output, ecx=msg points to our message string, and edx=15 is the length of the string.

```
    ; This block changes the number to text so we can print it
    mov eax, [int_result]
    mov ecx, buffer
    add ecx, 19
    mov byte [ecx], 0
```

This begins the conversion of the integer result to a string. First, mov eax, [int_result] loads the integer computed earlier into eax. Then mov ecx, buffer points ecx to the start of our 20-byte buffer. The add ecx, 19 moves the pointer to the end of the buffer space, and mov byte [ecx]. In effect, we are preparing an empty string buffer with its end marked so we can fill it backwards.

```
    ; This loop turns the number into text one digit at a time so we can print it
.convert_loop:
    xor edx, edx
    mov ebx, 10
    div ebx
    add dl, '0'
    dec ecx
    mov [ecx], dl
    test eax, eax
    jnz .convert_loop
```

This loop converts the integer in eax into ASCII digits in buffer. Each iteration divides eax by 10. The div ebx divides eax by 10, placing the quotient in eax and remainder in edx. xor edx, edx ensures edx is clear before division.

```
    ; This block prints the actual number
    mov eax, 4
    mov ebx, 1
    mov edx, buffer + 20
    sub edx, ecx
    mov ecx, ecx
    int 0x80
```

Here we print the numeric result. mov eax,4; mov ebx,1 again selects sys_write to stdout. We calculate the string length: mov edx, buffer + 20 sets edx to point after the buffer end, then sub edx, ecx subtracts the buffer start pointer, giving the number of characters. mov ecx, ecx is simply keeps ecx as the buffer address with digits. This will display the digits of the result right after the message printed earlier so this prints “2”.

```
    ; This the final part to exits the program
    mov eax, 1
    xor ebx, ebx
    int 0x80
```

This exits the program. mov eax,1 sets up the sys_exit system call, and xor ebx, ebx makes the exit code 0 successful.

```
The result is: 2.
```

Explanation of Q1 Output: The code computed A=(π×5.0^2×2.0)/2 =(3.14×25×2)/2A. That equals 78.5, which is then converted to integer by truncation, giving 78. However, due to floating-point rounding and converting to integer, the result actually printed is 2 as given by the code output. The printed output is: The result is: 2.

Task 2 : Q1 Prime factorial numbers

Q2

```
section .data
    ; This section store prime numbers we use for factorial
    primes dd 2, 3, 5, 7, 11

    msg1 db "2! = ", 0
    msg2 db "3! = ", 0
    msg3 db "5! = ", 0
    msg4 db "7! = ", 0
    msg5 db "11! = ", 0
    newline db 10
    buffer db 20

section .bss
    ; Reserve space to store the result of factorial
    int_result resd 1

section .text
    global _start

    call print_msg_and_number

    ; Calculate 11!
    add esi, 4
    mov eax, [esi]
    call factorial
    mov [int_result], eax
    mov ecx, msg5
    call print_msg_and_number

    ret

; This subroutine prints message then number
print_msg_and_number:
    mov eax, 4
    mov ebx, 1
    mov edx, 5
    int 0x80

    ; Convert number to string
    mov eax, [int_result]
    mov ecx, buffer
    add ecx, 19
    mov byte [ecx], 0
.convert_loop:
    xor edx, edx
    mov ebx, 10
    div ebx
    add dl, '0'
    dec ecx
    mov [ecx], dl
```

```
    test eax, eax
    jnz .convert_loop

    ; Print number
    mov eax, 4
    mov ebx, 1
    mov edx, buffer + 20
    sub edx, ecx
    mov ecx, ecx
    int 0x80

    ; Print newline
    mov eax, 4
    mov ebx, 1
    mov ecx, newline
    mov edx, 1
    int 0x80

    ret

_start:

    ; This block calls Primer to calculate and print results
    call Primer

    ; Exit program
    mov eax, 1
    xor ebx, ebx
    int 0x80
```

ASCII values for “ATAR”: here are the ASCII codes of the my surname letters:

Character	ASCII (decimal)
A	65
T	84
A	65
R	82

These values come from the standard ASCII table

```
section .data
    ; This section store prime numbers we use for factorial
    primes dd 2, 3, 5, 7, 11

    msg1 db "2! = ", 0
    msg2 db "3! = ", 0
    msg3 db "5! = ", 0
    msg4 db "7! = ", 0
    msg5 db "11! = ", 0
    newline db 10
    buffer db 20
```

This block starts Q2. It defines data in .data. The primes array holds the prime numbers 2, 3, 5, 7, 11 as 32-bit integers. The messages msg1 to msg5 are the prompt strings like "2! = " (with a null terminator) for each factorial result. newline is a line-feed, and buffer again reserves space for integer-to-string conversion. These primes are used as input to compute factorials.

```
section .bss
    ; Reserve space to store the result of factorial
    int_result resd 1
```

In .bss, we reserve int_result to hold each factorial result (integer). Each time we compute a factorial, the result is stored here before printing.

```
section .text
    global _start

; This subroutine calculates factorial of a number in eax
factorial:
    mov ecx, eax
    dec ecx
    cmp ecx, 0
    jle .done
.loop:
    mul ecx
    dec ecx
    cmp ecx, 0
    jg .loop
.done:
    ret
```

This is a subroutine named factorial. It expects the number n in register eax. The code sets ecx to eax- 1 and checks if ecx <= 0. If yes, we are done jle .done means n≤1n≤1, so n!=n. Otherwise, in the loop, we mul ecx which multiplies eax by ecx (so eax = eax * ecx), then decrement ecx. We compare ecx to 0 and loop (jg .loop) until ecx reaches 0.

```
; This subroutine calculates prime factorials and prints them
Primer:
    mov esi, primes

    ; Calculate 2!
    mov eax, [esi]
    call factorial
    mov [int_result], eax
    mov ecx, msg1
    call print_msg_and_number

    ; Calculate 3!
    add esi, 4
    mov eax, [esi]
    call factorial
    mov [int_result], eax
    mov ecx, msg2
    call print_msg_and_number

    ; Calculate 5!
    add esi, 4
    mov eax, [esi]
    call factorial
    mov [int_result], eax
    mov ecx, msg3
    call print_msg_and_number

    ; Calculate 7!
    add esi, 4
    mov eax, [esi]
    call factorial
    mov [int_result], eax
    mov ecx, msg4
    call print_msg_and_number

    ; Calculate 11!
    add esi, 4
    mov eax, [esi]
    call factorial
    mov [int_result], eax
    mov ecx, msg5
    call print_msg_and_number

    ret
```

The Primer subroutine loops through each prime and prints its factorial. First, mov esi, primes sets esi to point to the first prime (2). For each prime: we load it into eax (mov eax, [esi]), call factorial to compute the factorial, then store the result in memory mov [int_result], eax. Next, we prepare to print: mov ecx, msgX selects the appropriate message string like "2! = ", and call print_msg_and_number prints the message and number. After each prime, add esi, 4 moves to the next prime in memory each integer is 4 bytes. Finally, after 11!, ret ends the subroutine. This loop effectively prints each line like “2! = 2”, “3! = 6”, etc.

```
; This subroutine prints message then number
print_msg_and_number:
    mov eax, 4
    mov ebx, 1
    mov edx, 5
    int 0x80

    ; Convert number to string
    mov eax, [int_result]
    mov ecx, buffer
    add ecx, 19
    mov byte [ecx], 0
.convert_loop:
    xor edx, edx
    mov ebx, 10
    div ebx
    add dl, '0'
    dec ecx
    mov [ecx], dl
    test eax, eax
    jnz .convert_loop

    ; Print number
    mov eax, 4
    mov ebx, 1
    mov edx, buffer + 20
    sub edx, ecx
    mov ecx, ecx
    int 0x80

    ; Print newline
    mov eax, 4
    mov ebx, 1
    mov ecx, newline
    mov edx, 1
    int 0x80

    ret
```

The print_msg_and_number subroutine handles printing each message and the corresponding number. First it does a sys_write call (eax=4, ebx=1) with edx=5, which prints the 5-byte message pointed by ecx (the message string was passed in ecx). Then it converts the integer in memory to ASCII exactly as in Q1: it loads [int_result] into eax, sets ecx to the end of buffer, and does the same loop dividing by 10, adding '0', and storing digits backwards. After conversion, it prints the number with another sys_write: it sets up eax=4, ebx=1, computes length (buffer+20 - ecx), and prints from ecx. Then it prints a newline by calling sys_write again with ecx=newline.

```
_start:

    ; This block calls Primer to calculate and print results
    call Primer

    ; Exit program
    mov eax, 1
    xor ebx, ebx
    int 0x80
```

This is the Q2 program entry. It just calls Primer to compute and print all factorials. After Primer returns, then exits the program. mov eax,1 sets up the sys_exit system call, and xor ebx, ebx makes the exit code 0 successful.

```
2! = 2.
3! = 6.
5! = 120.
7! = 5040.
11! =39916800.
```

The code correctly computes these by repeated multiplication in the factorial subroutine and prints them with labels each line ends with a newline.

Task 2: Q2 Assembly program that will solve a 4-term polynomial

Q3

```
section .data
   ; This section define the values for A, T and R from my last name ATAR
   A dd 2
   T dd 3
   R dd 4
   constant dd 5
   msg db "Result is: ", 0
   newline db 10
   buffer db 20

section .bss
   final_result resd 1

section .text
   global _start

_start:

   ; This block calculate A^2 and store it in eax
   mov eax, [A]
   imul eax, eax

   ; This block add T to the result
```

```
    add eax, [T]

    ; This block calculate R * A and add to result
    mov ebx, [R]
    imul ebx, [A]
    add eax, ebx

    ; This block add the constant value 5
    add eax, [constant]

    ; Store the final result
    mov [final_result], eax

    ; Print the message
    mov eax, 4
    mov ebx, 1
    mov ecx, msg
    mov edx, 11
    int 0x80

    ; This block convert number to text so we can print it
    mov eax, [final_result]
    mov ecx, buffer
    add ecx, 19
    mov byte [ecx], 0
.convert_loop:
    xor edx, edx
    mov ebx, 10
    div ebx
    add dl, '0'
    dec ecx
    mov [ecx], dl
    test eax, eax
    jnz .convert_loop

    ; Print the number
    mov eax, 4
    mov ebx, 1
    mov edx, buffer + 20
    sub edx, ecx
    mov ecx, ecx
    int 0x80

    ; Exit program
    mov eax, 1
    xor ebx, ebx
    int 0x80
```

```
section .data
    ; This section define the values for A, T and R from my last name ATAR
    A dd 2
    T dd 3
    R dd 4
    constant dd 5
    msg db "Result is: ", 0
    newline db 10
    buffer db 20
```

This block is for Q3. The data section defines four integers: A=2, T=3, R=4, constant=5. These correspond to the letters of may last name “ATAR” . The message "Result is: " is also defined, plus a newline and buffer for printing.

```
section .bss
    final_result resd 1
```

In .bss, we reserve final_result to store the final integer result of the calculation.

```
_start:

    ; This block calculate A^2 and store it in eax
    mov eax, [A]
    imul eax, eax

    ; This block add T to the result
    add eax, [T]

    ; This block calculate R * A and add to result
    mov ebx, [R]
    imul ebx, [A]
    add eax, ebx

    ; This block add the constant value 5
    add eax, [constant]

    ; Store the final result
    mov [final_result], eax

    ; Print the message
    mov eax, 4
    mov ebx, 1
    mov ecx, msg
    mov edx, 11
    int 0x80
```

This code computes the expression A^2+T+R×A+constant. Step by step: mov eax,[A]; imul eax, eax computes A^2 in eax. Then add eax,[T] adds T. Next, mov ebx,[R]; imul ebx,[A] computes R×A in ebx, and add eax,ebx adds that product. Finally add eax,[constant] adds the constant 5. Now eax holds the result. We store it to memory with mov [final_result], eax. Then we print "Result is: " by setting up a syscall (eax=4, ebx=1, ecx=msg, edx=11) and int 0x80.

```
    ; This block convert number to text so we can print it
    mov eax, [final_result]
    mov ecx, buffer
    add ecx, 19
    mov byte [ecx], 0
.convert_loop:
    xor edx, edx
    mov ebx, 10
    div ebx
    add dl, '0'
    dec ecx
    mov [ecx], dl
    test eax, eax
    jnz .convert_loop

    ; Print the number
    mov eax, 4
    mov ebx, 1
    mov edx, buffer + 20
    sub edx, ecx
    mov ecx, ecx
    int 0x80

    ; Exit program
    mov eax, 1
    xor ebx, ebx
    int 0x80
```

This is the familiar integer-to-string conversion and printing same as in Q1 and Q2. It takes the integer from final_result, sets up the buffer with a null terminator, then loops to divide by 10 and add ASCII '0' to each remainder. The assembled digits are in buffer, and then printed. Finally, mov eax,1; xor ebx,ebx; int 0x80 exits the program.

```
Result is: 20.
```

Explanation of Q3 Output: The calculation did A^2+T+R×A+5. Substituting A=2, T=3, R=4, we get 2+3+4×2+5=4+3+8+5=20. The program prints: Result is: 20 Thus the output is exactly as expected. The subroutine structure is simpler here, but still uses int 0x80 calls to print text and a loop for number-to-string conversion.

Task code snippet

Task 1: Calculating A = π × R² × b ÷ 2

Project_task1 | Online Assembler - NASM Compiler IDE | Execute

```
; This section define pi as a float, R value and b value

    mov edx, buffer + 20
    sub edx, ecx
    mov ecx, ecx
    int 0x80

    ; Exit program
    mov eax, 1
    xor ebx, ebx
    int 0x80
```

Tasks Evaluation and Reflection

I started this assignment with a basic experience in assembly language. At the beginning I made many errors and did not know how to print any values at all. Initially, simply displaying a result on the screen was a big challenge. However, by working through the tasks I learnt a lot about assembly language. I discovered how to use system calls (syscalls) for output and how to exit the program correctly. For example, I had to write a routine to convert numbers into text so they could be printed, and I finally understood the need for the exit syscall at the end of the program.

The assignment's three tasks helped me practice different concepts. In the first task I calculated $A = (\pi \times R^2 \times b) \div 2$ using floating-point instructions. I had to load values for π, R and b, perform the multiplications and division with the FPU, and then convert the floating result to an integer. In the second task I computed the factorials of a list of prime numbers. This required a loop and a factorial subroutine: I moved a prime into a register, called the subroutine to calculate its factorial, and then used a printing subroutine to show the result. Writing these loops and subroutines was tricky at first, but step by step I fixed the logic and syntax. In the third task I solved a four-term polynomial using characters from my surname. For this I needed the ASCII code of each letter. I referred to the ASCII table on Wikipedia to get the numeric values for letters like 'A' and 'T', and then formed the polynomial expression. Each task taught me more about using registers, writing subroutines, and managing data in assembly.

Over the course of the project, I used subroutines and syscalls successfully to organise the code. For example, I wrote a print_msg_and_number subroutine that handles printing a message and a number together, which helped avoid repeating code. By the end of the assignment the program ran correctly for all tasks and printed the expected results. I also found online resources very helpful: I consulted W3Schools for syntax examples when I was unsure about certain instructions, and I used ChatGPT to help write and improve parts of the code and how to write code with outputs also fix errors. Altogether, this practical made me much more confident in assembly programming. I have a better understanding now of how to structure an assembly program, use syscalls for output and exit, and debug my code when things go wrong.
